

2.0插针引出的5个GPIO:  
PA15、PC6支持高级定时器全功能:  
输入捕获、OC或PWM输出或不输出  
PB7、PB6可配置为USART1与不输出  
捕获引脚连接GPS  
PPS, 配置好GPS后将PB7改为I2C1\_S  
DA, 只用一个引脚接受PPS脉冲,  
用PB6、PB7配置为I2C1 RTC模块修  
正时间, RTC的脉冲占用一个外部  
中断引脚  
剩余最后一个引脚可用于GPS复位

▲ STM内部有弱上拉电阻到VDD  
外部千万不能再接一个上拉电阻到VbatWeak或3V3，VDD会倒灌到上拉的电压轨，就用内部弱上拉好了

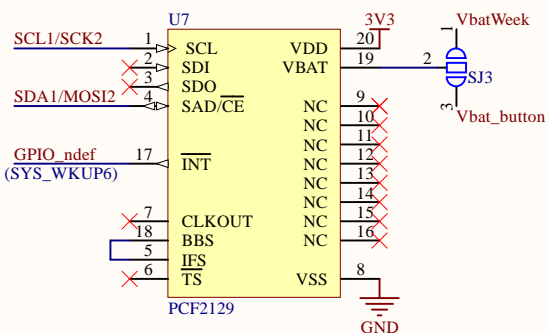

▲ WP为写保护引脚，高电平有效（禁止写，只读），低电平失效（可读可写）

### ▲ 纽扣电池跳线充电电路

▲ 传感器配置和记录的数据写在EEPROM里（经常擦写）  
G031自身菜单的参数写在片内Flash里（不经常擦写）

那么G031控制PWR\_HOLD的GPIO配置为模拟输入模式，于是就关闭VBAT电源，继而3.3V电源也关闭，此模式下只有G031和加速度计有电源，此模式进入STM32的STOP模式，那么如何周期性唤醒（不通过加速度计的INT）？是不是必须用SYS\_SKUP的上升沿唤醒？那三个按钮不是得都另一头接VCC了？按钮按下打开电源mOS不就冲突了？

▲TextRB521S30 SOD523肖特基二极管压降,  $T_J = 25$ 摄氏度, G031电流 1mA-11mA, 压降0.2-0.3V, 从3.3V压降后给G031供电, 电压最低为3.0V (主频2-64MHz)
